The Puzzling Effects of Monetary Policy in VARs: Invalid Identification or Missing Information?

Mark Kerstenfischer¹

¹Deutsche Bundesbank

August 2018

The views expressed in this paper do not necessarily reflect those of the Deutsche Bundesbank.

Puzzling Effects of Monetary VARs

due to invalid identification scheme?

Motivation

Empirical
Methods

Results

Conclusion

Robustness

Details

Dynamic Factor
Model

Identification

Nonfundamental-
ness

Contractionary monetary policy shocks

- increase prices ('price puzzle')
- have hump-shaped effect on FX rates ('delayed overshooting')
- do not affect credit spreads

Main suspected culprit: Recursive (Cholesky) identification

- imposes invalid timing restrictions

Solution: external instruments (*Gertler and Karadi, 2015*)

- high-frequency futures around FOMC decisions
- no restrictions on contemporaneous shock effects

Model

Identification

Nonfundamental-
ness

But...

Puzzling VAR results may also be due to **Missing Information**

- VARs suffer curse of dimensionality
inevitable proliferation of unknown parameters as further variables (or lags) are added
- may lead to nonfundamentality

⇒ invalidates results, **regardless of identification scheme**

Solution: enlarge information set

- FAVAR: add factors to observable variables
- DFM: assume all factors are unobservable

My research question: what explains puzzling VAR results?

- invalid identification?
- or missing information?

Approach: start with basic Cholesky VAR and

- apply external instrument identification
- expand information set via factors

→ check which puzzles these methods are able to solve

Result: missing information is key

In a joint paper with Lucia Alessi, we show

- even with high-frequency instrument, puzzling VAR results :
 - IP & CPI expand after contractionary shock
 - Stocks & credit spreads barely react (or exhibit wrong sign)
as in Jarocinski & Karadi, ECB WP 2018
- using same instrument in factor model yields intuitive results
 - solves IP & CPI puzzle
 - yields stronger & more rapid asset price effects

See "The Response of Asset Prices to Monetary Policy Shocks: Stronger Than Thought",
Alessi & Kerssenfischer (2018)

Rewrite

$$u_t = H\epsilon_t = [H_1 \dots H_q] \begin{pmatrix} \epsilon_{1t} \\ \vdots \\ \epsilon_{qt} \end{pmatrix} \quad \text{and w.l.g. pick } \epsilon_{1t} \text{ as the mon.pol. shock}$$

Given an instrumental variable Z_t that meets

- relevance condition: $E(\epsilon_{1t}Z_t) = \alpha \neq 0$
- and exogeneity condition: $E(\epsilon_{jt}Z_t) = 0, j = 2, \dots, q$

we get

$$\begin{bmatrix} E(u_{1t}Z_t) \\ E(u_{\bullet t}Z_t) \end{bmatrix} = E(u_tZ_t) = E(H\epsilon_tZ_t) = [H_1 H_{\bullet}] \begin{bmatrix} E(\epsilon_{1t}Z_t) \\ E(\epsilon_{\bullet t}Z_t) \end{bmatrix} = H_1 \alpha$$

→ In practice: estimate H_1 by regressing instrument Z_t on reduced form shocks u_t

Dynamic Factor
Model

Identification

Nonfundamental-
ness

Y_t : economic variables (production, prices, interest rates, ...)
 ϵ_t : shocks (technology, fiscal and monetary policy, ...)

$$\Rightarrow Y_t = B(L)\epsilon_t$$

Intuition: the **economy** is driven by exogenous **structural shocks** and **agent's reaction** to them (households, firms, ...)

- 1 estimate reduced form VAR: $A(L)Y_t = u_t$
- 2 obtain u_t and A_j by OLS (equation by equation)
- 3 apply identification restrictions B_0 (Cholesky, signs, long-run, ...)

→ structural shocks $\epsilon_t = B_0^{-1}u_t$

→ structural IRFs $B(L) = A(L)^{-1}B_0$

Nonfundamentalness in small-scale VARs

VAR models: the problem

Motivation

Empirical
Methods

Results

Conclusion

Robustness

Details

Dynamic Factor
Model

Identification

Nonfundamental-
ness

Assumption (implicit): structural shocks can be recovered using present and past values of economic time series. But:

- Economic agents incorporate large information sets
 - ECB e.g. monitors more variables than just GDP & HICP
- VARs typically capture only a few variables

⇒ agent's information set > econometrician's information set

⇒ **Nonfundamentalness**

Intuitively: VAR variables Y_t do not contain enough information to recover structural shocks u_t and IRFs $B(L)$

Technically: structural moving average representation is not invertible

Basic idea of **factor models**:

- expand the information space (drastically)
- usually >100 variables vs. 4-8 in VARs
